

# COT 6405 Introduction to Theory of Algorithms

Final exam review

# About the final exam

- The final will cover everything we have learned so far.
- Closed books, closed computers, and closed notes.
- A front-side cheat sheet is allowed
- The final grades will be curved

# Question type

- Possible types of questions:
  - proofs
  - General questions and answer
  - Problems/computational questions
- The content covered by midterms I and II takes 60%
- The content we studied after midterm II takes 40%

# Quick summary of previous content

- How to solve the recurrences
  - Substitution method
  - Tree method
  - Master theorem
- Comparison based sorting algorithms
  - Merge sort, quick sort, and Heap sort
- Linear time sorting algorithms
  - Counting sort, Bucket sort, and Radix sort

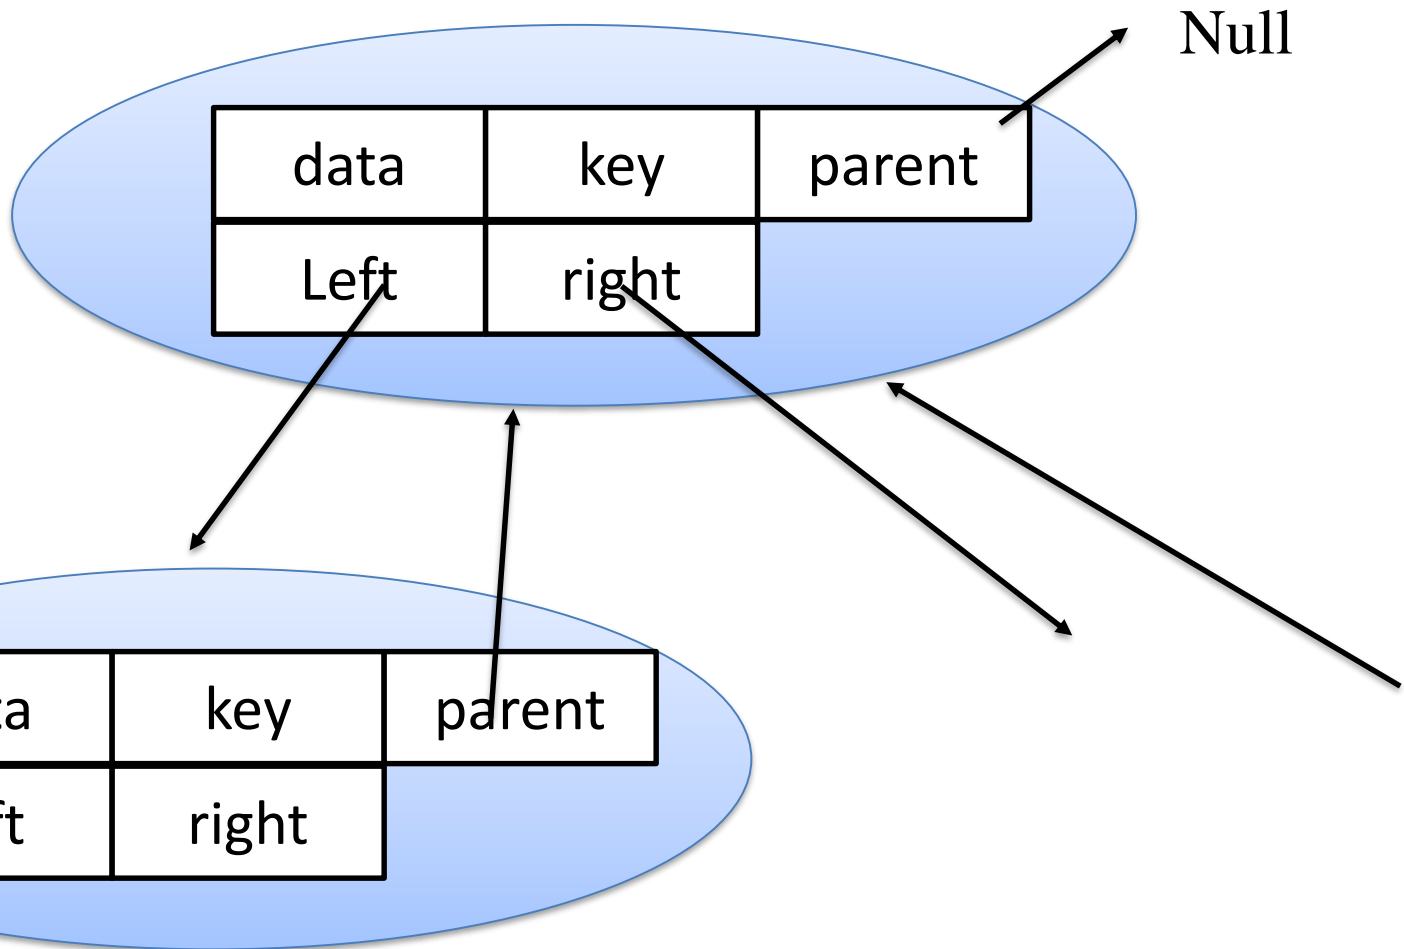

# Quick summary (cont'd)

- Basic heap operations:
  - Build-Max-Heap, Max-Heapify
- Order statistics
  - How to find the k-th largest element : BigFive algorithm
- Hash tables
  - The definition and how it works
  - Hash function  $h$ : Mapping from Universe  $U$  to the slots of a hash table  $T$

# Binary Search Trees

- Binary Search Trees (BSTs) are an important data structure for dynamic sets
- In addition to satellite data, nodes have:
  - **key**: an identifying field inducing a total ordering
  - **left**: pointer to a left child (may be NULL)
  - **right**: pointer to a right child (may be NULL)
  - **p**: pointer to a parent node (NULL for root)

# Node implementation

# Binary Search Trees

- BST property: Let  $x$  be a node in a binary search tree. If  $y$  is a node in the left subtree of  $x$ , then  $y.\text{key} < x.\text{key}$ . If  $y$  is a node in the right subtree of  $x$ , then  $y.\text{key} > x.\text{key}$ . Different BSTs can be constructed to represent the same set of data

Average case  $O(\lg n)$

worst case  $O(n)$

# Walk on BST

- A: prints elements in sorted (increasing) order  
`InOrderTreeWalk (x)`  
`InOrderTreeWalk (x.left) ;`  
`print (x) ;`  
`InOrderTreeWalk (x.right) ;`
- This is called an inorder tree walk
  - *Preorder tree walk*: print root, then left, then right
  - *Postorder tree walk*: print left, then right, then root

# Operations on BSTs: Search

- Given a key and a pointer to a node, returns an element with that key or NULL:

```
TreeSearch(x, k)
```

```
    if (x = NULL or k = x.key)
```

```
        return x;
```

```
    if (k < x.key)
```

```
        return TreeSearch(x.left, k);
```

```
    else
```

```
        return TreeSearch(x.right, k);
```

# Operations on BSTs: Search

- Here's another function that does the same

Iterative-Tree-Search (**x**, **k**)

```
while (x != NULL and k != x.key)
    if (k < x.key)
        x = x.left;
    else
        x = x.right;
return x;
```

# BST Operations: Minimum

- How can we implement a Minimum() query?

```
TREE_MINIMUM(x)
```

```
    while x.lef <> NIL
```

```
        x = x.left
```

```
    Return x
```

- What is the running time?
- Minimum → Find the leftmost node in tree
- Maximum → find the rightmost node in the tree

# BST Operations: Successor

- Successor of  $x$ : the smallest key greater than  $key[x]$ .
- What is the successor of node 3? Node 15? Node 13?
- What are the general rules for finding the successor of node  $x$ ? (hint: two cases)

# BST Operations: Successor

- Two cases:
  - $x$  has a right subtree: its successor is minimum node in right subtree
  - $x$  has no right subtree:  $x$  must be on the left subtree of the successor such that  $x \leq \text{successor}$ . So the successor is the first ancestor of  $x$  whose left child is an ancestor of  $x$  (or  $x$ )
    - Intuition: As long as you move to the left up the tree, you're visiting smaller nodes.

# BST Operations: predecessor

- Two cases:
  - $x$  has a left subtree: its predecessor is maximum node in left subtree
  - $x$  has no left subtree:  $x$  must be on the right subtree of the predecessor such that  $x \geq$  predecessor. So the predecessor is the first ancestor of  $x$  whose right child is an ancestor of  $x$  (or  $x$ )

# Operations of BSTs: Insert

- Adds an element  $x$  to the tree
  - $\rightarrow$  the binary search tree property continues to hold
- The basic algorithm
  - Like the search procedure above
  - Use a “trailing pointer” to keep track of where you came from
    - like inserting into singly linked list

# BST Operations: Delete

- Several cases:

- x has no children:

- Remove x
- Set parent's link NULL

- x has one child:

- Replace x with its child
- Set the child's link NULL

- x has two children:

- replace x with its successor
- Perform case 0 or 1 to delete it

**Example: delete K  
or H or B**

# Elementary Graph Algorithms

- How to represent a graph?
  - Adjacency lists
  - Adjacency matrix
- How to search a graph?
  - Breadth-first search
  - Depth-first search

# Graphs: Adjacency Matrix

- Example:

A	1	2	3	4
1	0	1	1	0
2	0	0	1	0
3	0	0	0	0
4	0	0	1	0

# Graphs: Adjacency List

- Undirected

(a)

(b)

- Directed Graph

(a)

(b)

# Graphs: Adjacency List

- How much storage is required?
  - The degree of a vertex  $v = \#$  incident edges
    - Two edges are called incident, if they share a vertex
    - Directed graphs have in-degree, out-degree
  - For directed graphs, # of items in adjacency lists is  $\sum \text{out-degree}(v) = |E|$   
takes  $\Theta(V + E)$  storage
  - For undirected graphs, # items in adjacency lists is  $\sum \text{degree}(v) = 2 |E|$   
also  $\Theta(V + E)$  storage
- So: Adjacency lists take  $O(V+E)$  storage

# Breadth-First Search (BFS)

- “Explore” a graph, turning it into a tree
  - One vertex at a time
  - Expand frontier of explored vertices across the breadth of the frontier
- Builds a tree over the graph
  - Pick a source vertex to be the root
  - Find (“discover”) its children, then their children, etc.

# Breadth-First Search

```
BFS(G, s) {
    initialize vertices;
    Q = {s};
    while (Q not empty) {
        u = Dequeue(Q);
        for each v ∈ G.adj[u] {
            if (v.color == WHITE)
                v.color = GREY;
                v.d = u.d + 1;
                v.p = u;
                Enqueue(Q, v);
        }
        u.color = BLACK;
    }
}
```

# Time analysis

- The total running time of BFS is  $O(V + E)$
- Proof:
  - Each vertex is dequeued at most once. Thus, total time devoted to queue operations is  $O(V)$ .
  - For each vertex, the corresponding adjacency list is scanned at most once. Since the sum of the lengths of all the adjacency lists is  $\Theta(E)$ , the total time spent in scanning adjacency lists is  $O(E)$ .
  - Thus, the total running time is  $O(V+E)$

# Breadth-First Search: Properties

- BFS calculates the shortest-path distance to the source node
  - Shortest-path distance  $\delta(s,v)$  = minimum number of edges from  $s$  to  $v$ , or  $\infty$  if  $v$  not reachable from  $s$
- BFS builds breadth-first tree, in which paths to root represent shortest paths in  $G$ 
  - Thus, we can use BFS to calculate a shortest path from one vertex to another in  $O(V+E)$  time

# Depth-First Search

- Depth-first search is another strategy for exploring a graph
  - Explore “deeper” in the graph whenever possible
  - Edges are explored out of the most recently discovered vertex  $v$  that still has unexplored edges
    - Timestamp to help us remember who is “new”
  - When all of  $v$ 's edges have been explored, backtrack to the vertex from which  $v$  was discovered

# Depth-First Search: The Code

DFS(G)

```
{
  for each vertex  $u \in G.V$ 
  {
     $u.color = WHITE$ 
     $u.\pi = NIL$ 
  }
  time = 0
  for each vertex  $u \in G.V$ 
  {
    if ( $u.color == WHITE$ )
      DFS_Visit(G, u)
  }
}
```

DFS\_Visit(G, u)

```
{
  time = time + 1
   $u.d = time$ 
   $u.color = GREY$ 
  for each  $v \in G.Adj[u]$ 
  {
    if ( $v.color == WHITE$ )
       $v.\pi = u$ 
      DFS_Visit(G, v)
  }
   $u.color = BLACK$ 
  time = time + 1
   $u.f = time$ 
}
```

# DFS: running time (cont'd)

- How many times will DFS\_Visit() actually be called?
  - The loops on lines 1–3 and lines 5–7 of DFS take time  $\Theta(V)$ , exclusive of the time to execute the calls to DFS-VISIT.
  - DFS-VISIT is called exactly once for each vertex  $v$
  - During an execution of DFS-VISIT( $v$ ), the loop on lines 4–7 is executed  $|Adj[v]|$  times.
  - $\sum_{v \in V} |Adj[v]| = \Theta(E)$
  - Total running time is  $\Theta(V + E)$

# DFS: Different Types of edges

- DFS introduces an important distinction among edges in the original graph:
  - Tree edge: encounter new vertex
  - Back edge: from a descendent to an ancestor
  - Forward edge: from an ancestor to a descendent
  - Cross edge: between a tree or subtrees
- Note: tree & back edges are important
  - most algorithms don't distinguish forward & cross

# Minimum Spanning Tree

- Problem:
  - given a connected, undirected, weighted graph  
 $G = (V, E)$
  - find a spanning tree using edges that connects all nodes with a minimal total weight  $w(T) = \text{SUM}(w[u,v])$ 
    - $w[u,v]$  is the weight of edge  $(u,v)$
- Objectives: we will learn
  - Generic MST
  - Kruskal's algorithm
  - Prim's algorithm

# Growing a minimum spanning tree

- Building up the solution
  - We will build a set  $A$  of edges
  - Initially,  $A$  has no edges.
  - As we add edges to  $A$ , maintain a loop invariant
- Loop invariant:  $A$  is a subset of some MST
  - Add only edges that maintain the invariant
  - Definition: If  $A$  is a subset of some MST, an edge  $(u, v)$  is **safe** for  $A$ , if and only if  $A \cup \{(u, v)\}$  is also a subset of some MST
  - So we will add only safe edges

# Generic MST algorithm

**GENERIC-MST**( $G, w$ )

$A = \emptyset$

**while**  $A$  is not a spanning tree

**find** an edge  $(u, v)$  that is safe for  $A$

$A = A \cup \{(u, v)\}$

**return**  $A$

# How do we find safe edges?

- Let edge set  $A$  be a subset of some MST
- $(S, V - S)$  be a cut that respects edge set  $A$ 
  - No edges in  $A$  crosses the cut
- $(u, v)$  be a light edge crossing cut  $(S, V - S)$ .
- Then,  $(u, v)$  is **safe** for  $A$ .

# MST: optimal substructure

- MSTs satisfy the optimal substructure property: an optimal tree is composed of optimal subtrees
  - Let  $T$  be an MST of  $G$  with an edge  $(u,v)$  in the middle
  - Removing  $(u,v)$  partitions  $T$  into two trees  $T_1$  and  $T_2$
  - Claim:  $T_1$  is an MST of  $G_1 = (V_1, E_1)$ , and  $T_2$  is an MST of  $G_2 = (V_2, E_2)$

# Kruskal's algorithm

- Starts with each vertex being its own component
- Repeatedly merges two components into one by choosing the light edge that connects them
- Scans the set of edges in monotonically increasing order by weight
- Uses a disjoint-set data structure to determine whether an edge connects vertices in different components.

# Disjoint Sets Data Structure

- A disjoint-set is a collection  $C = \{S_1, S_2, \dots, S_k\}$  of distinct dynamic sets
- Each set is identified by a member of the set, called representative.
- Disjoint set operations:
  - MAKE-SET(x): create a new set with only x
    - assume x is not already in some other set.
  - UNION(x,y): combine the two sets containing x and y into one new set.
    - A new representative is selected.
  - FIND-SET(x): return the representative of the set containing x.

# Kruskal's Algorithm

```
Kruskal(G, w)
{
    A =  $\emptyset$ ;
    for each v  $\in$  G.V
        Make-Set(v);
    sort G.E by non-decreasing order by weight w
    for each (u,v)  $\in$  G.E (in sorted order)
        if FindSet(u)  $\neq$  FindSet(v)
            A = A  $\cup$  {{u,v}};
            Union(u, v);
}
```

# Kruskal's Algorithm: Running Time

- Initialize A:  $O(1)$
- First for loop:  $|V|$  MAKE-SETS
- Sort E:  $O(E \lg E)$
- Second for loop:  $O(E)$  FIND-SETS and UNIONS
- **$O(V) + O(E \alpha(V)) + O(E \lg E)$** 
  - Since G is connected,  $|E| \geq |V| - 1 \Rightarrow O(E \alpha(V)) + O(E \lg E)$
  - $\alpha(|V|) = O(\lg V) = O(\lg E)$
  - Therefore, the total time is  $O(E \lg E)$
  - $|E| \leq |V|^2 \Rightarrow \lg |E| = O(2 \lg V) = O(\lg V)$
  - Therefore,  **$O(E \lg V)$**  time

# Prim's algorithm

- Build a tree  $A$  ( $A$  is always a tree)
  - Starts from an arbitrary “root”  $r$ .
  - At each step, find a light edge crossing the cut  $(V_A, V - V_A)$ , where  $V_A =$  vertices that  $A$  is incident on.
  - Add this light edge to  $A$ .
- GREEDY CHOICE:
  - add min weight to  $A$*
- Use a priority queue  $Q$  to quickly find the light edge

# Prim's Algorithm

```
MST-Prim( $G, w, r$ )
  for each  $u \in G.V$ 
     $u.key = \infty$ 
     $u.\pi = NIL$ 
   $r.key = 0$ 
   $Q = G.V$ 
  while ( $Q$  not empty)
     $u = \text{ExtractMin}(Q)$ 
    for each  $v \in G.Adj[u]$ 
      if ( $v \in Q$  and  $w(u, v) < v.key$  )
         $v.\pi = u$ 
         $v.key = w(u, v)$ 
```

# Prim's Algorithm: running time

- We can use the BUILD-MIN-HEAP procedure to perform the initialization in lines 1–5 in  $O(V)$  time
- EXTRACT-MIN operation is called  $|V|$  times, and each call takes  $O(\lg V)$  time, the total time for all calls to EXTRACT-MIN is  $O(V \lg V)$

# Running time (cont'd)

- The for loop in lines 8–11 is executed  $O(E)$  times altogether, since the sum of the lengths of all adjacency lists is  $2|E|$ .
  - Lines 9 -10 take constant time
  - line 11 involves an implicit DECREASE-KEY operation on the min-heap, which takes  $O(\lg V)$  time
- Thus, the total time for Prim's algorithm is  $O(V) + O(V \lg V) + O(E \lg V) = O(E \lg V)$ 
  - The same as Kruskal's algorithm

# Single source shortest path problem

- Problem: given a weighted directed graph  $G$ , find the minimum-weight path from a given source vertex  $s$  to another vertex  $v$ 
  - “Shortest-path”  $\rightarrow$  Weight of the path is minimum
  - Weight of a path is the sum of the weight of edges

# Shortest path properties

- Optimal substructure property: any subpath of a shortest path is a shortest path
- In graphs with negative weight cycles, some shortest paths will not exist:
- Negative weight edges are ok for some cases
- Shortest paths cannot contain cycles

# Initialization

- All the shortest-paths algorithms start with INIT-SINGLE-SOURCE

INIT-SINGLE-SOURCE( $G, s$ )

**for** each vertex  $v \in G.V$

**$v.d = \infty$**

**$v.\pi = \text{NIL}$**

**$s.d = 0$**

# Relaxation: reach v by u

```
Relax(u, v, w) {  
    if (v.d > u.d + w(u, v))  
        v.d = u.d + w(u, v)  
  
    v.π = u  
}
```

⋮ Relax  
▼

decrease by 2

⋮ Relax  
▼

unchanged

# Properties of shortest paths

- Triangle inequality

For all  $(u, v) \in E$ , we have  $\delta(s, v) \leq \delta(s, u) + w(u, v)$ .

**Proof** Weight of shortest path  $s \rightsquigarrow v$  is  $\leq$  weight of any path  $s \rightsquigarrow v$ . Path  $s \rightsquigarrow u \rightarrow v$  is a path  $s \rightsquigarrow v$ , and if we use a shortest path  $s \rightsquigarrow u$ , its weight is  $\delta(s, u) + w(u, v)$ . ■

# Upper-bound property

- Always have  $v.d \geq \delta(s,v)$ 
  - Once  $v.d = \delta(s,v)$ , it never changes
- Proof: Initially, it is true:  $v.d = \infty$
- Supposed there is vertex such that  $v.d < \delta(s,v)$
- Without loss of generality,  $v$  is the first vertex for this happens
- Let  $u$  be the vertex that causes  $v.d$  to change
- Then  $v.d = u.d + w(u,v)$
- So,  $v.d < \delta(s,v) \leq \delta(s,u) + w(u,v) < u.d + w(u,v)$
- Then  $v.d < u.d + w(u,v)$
- Contradict to  $v.d = u.d + w(u,v)$

# No-path property

- If  $\delta(s,v) = \infty$ , then  $v.d = \infty$  always
- Proof:  $v.d \geq \delta(s,v) = \infty \rightarrow v.d = \infty$

# Convergence property

If  $s \rightsquigarrow u \rightarrow v$  is a shortest path,  $u.d = \delta(s, u)$ , and we call  $RELAX(u, v, w)$ , then  $v.d = \delta(s, v)$  afterward.

**Proof** After relaxation:

$$\begin{aligned} v.d &\leq u.d + w(u, v) && \text{(RELAX code)} \\ &= \delta(s, u) + w(u, v) \\ &= \delta(s, v) && \text{(lemma—optimal substructure)} \end{aligned}$$

Since  $v.d \geq \delta(s, v)$ , must have  $v.d = \delta(s, v)$ . ■

When the “if” condition is true,  $v.d = u.d + w(u, v)$

When the “if” condition is false,  $v.d \leq u.d + w(u, v)$

# Path relaxation property

Let  $p = \langle v_0, v_1, \dots, v_k \rangle$  be a shortest path from  $s = v_0$  to  $v_k$ . If we relax, in order,  $(v_0, v_1), (v_1, v_2), \dots, (v_{k-1}, v_k)$ , even intermixed with other relaxations, then  $v_k.d = \delta(s, v_k)$ .

**Proof** Induction to show that  $v_i.d = \delta(s, v_i)$  after  $(v_{i-1}, v_i)$  is relaxed

**Basis:**  $i = 0$ . Initially,  $v_0.d = 0 = \delta(s, v_0) = \delta(s, s)$ .

**Inductive step:** Assume  $v_{i-1}.d = \delta(s, v_{i-1})$ . Relax  $(v_{i-1}, v_i)$ . By convergence property,  $v_i.d = \delta(s, v_i)$  afterward and  $v_i.d$  never changes. ■

# Bellman-Ford algorithm

//Allows negative-weight edges

**BellmanFord**(*G*, *w*, *s*)

INIT-SINGLE-SOURCE(*G*, *s*)

for *i*=1 to |*G.V*|-1

for each edge (*u,v*) ∈ *G.E*

Relax(*u*, *v*, *w*);

for each edge (*u,v*) ∈ *G.E*

if (*v.d* > *u.d* + *w(u,v)*)

return "no solution";

*Relaxation:*

Make |*V*|-1 passes,  
relaxing each edge

*Test for solution*  
*Under what condition*  
*do we get a solution?*

**Relax**(*u,v,w*): if (*v.d* > *u.d* + *w(u,v)*)

*v.d* = *u.d* + *w(u,v)*

# Running time

- Initialization:  $\Theta(V)$
- Line 2-4 :  $\Theta(E) * |V|-1$  passes
- Line 5-7 :  $O(E)$
- $O(VE)$

# Dijkstra's Algorithm

- Assumes **no negative-weight edges**.
- Maintains a vertex set  $S$  whose shortest path from  $s$  has been determined.
- Repeatedly selects  $u$  in  $V-S$  with minimum Shortest Path estimate (greedy choice).
- Store  $V-S$  in priority queue  $Q$ .

```
DIJKSTRA( $G, w, s$ )
Initialize-SINGLE-SOURCE( $G, s$ );
 $S = \emptyset$ ;
 $Q = G.V$ ;
while  $Q \neq \emptyset$ 
     $u = \text{Extract-Min}(Q)$ ;
     $S = S \cup \{u\}$ ;
    for each  $v \in G.\text{Adj}[u]$ 
        Relax( $u, v, w$ )
```

# Dijkstra's Running Time

- Extract-Min executed  $|V|$  time
- Decrease-Key executed  $|E|$  time
- Time =  $|V| T_{\text{Extract-Min}} + |E| T_{\text{Decrease-Key}}$
- Time =  $O(V \lg V) + O(E \lg V) = O(E \lg V)$

# Dynamic Programming (DP)

- Like divide-and-conquer, solve problem by combining the solutions to sub-problems.
- Divide-and-conquer vs. DP:
  - divide-and-conquer: Independent sub-problems
    - solve sub-problems independently and recursively, ( $\rightarrow$  so same sub-problems solved repeatedly)
  - DP: Sub-problems are dependent
    - sub-problems share sub-sub-problems
    - every sub-problem is solved just once
    - solutions to sub-problems are stored in a table and used for solving higher level sub-problems.

# Overview of DP

- Not a specific algorithm, but a technique (like divide-and-conquer).
- Doesn't really refer to computer programming
- Application domain of DP
  - Optimization problem: find a solution with the optimal (maximum or minimum) value

# Matrix-chain multiplication problem

- Given a chain  $\langle A_1, A_2, \dots, A_n \rangle$  of  $n$  matrices
  - where for  $i = 1, \dots, n$ , matrix  $A_i$  has dimension  $p_{i-1} \times p_i$
  - fully parenthesize the product  $A_1 A_2 \cdots A_n$  in a way that minimizes the number of scalar multiplications.
- What is the minimum number of multiplications required to compute  $A_1 \cdot A_2 \cdot \dots \cdot A_n$ ?
- What order of matrix multiplications achieves this minimum? This is our goal !

## Step 1: Find the structure of an optimal parenthesization

- Finding the optimal substructure and using it to construct an optimal solution to the problem based on optimal solutions to subproblems.

Both must be **Optimal** for sub-chain

$$((A_1 A_2 \cdots A_k)(A_{k+1} A_{k+2} \cdots A_n))$$

Then combine them for the original problem

- The key is to find  $k$  ; then, we can build the global optimal solution

## Step 2: A recursive solution to define the cost of an optimal solution

- Define  $m[i, j]$  = the minimum number of multiplications needed to compute the matrix  $A_{i..j} = A_i A_{i+1} \cdots A_j$
- Goal: to compute  $m[1, n]$
- Basis:  $m(i, i) = 0$ 
  - Single matrix, no computation
- Recursion: How to define  $m[i, j]$  recursively?
  - $((A_i A_2 \cdots A_k)(A_{k+1} A_{k+2} \cdots A_j))$

## Step2: Defining $m[i,j]$ Recursively

- Consider all possible ways to split  $A_i$  through  $A_j$  into two pieces:  $(A_i \cdot \dots \cdot A_k) \cdot (A_{k+1} \cdot \dots \cdot A_j)$
- Compare the costs of all these splits:
  - best case cost for computing the product of the two pieces
  - plus the cost of multiplying the two products
  - Take the best one
  - $m[i,j] = \min_k \{ m[i,k] + m[k+1,j] + p_{i-1}p_kp_j \}$

# Identify Order for Solving Subproblems

- Solve the subproblems (i.e., fill in the table entries) along the diagonal

	1	2	3	4	5
1	0				
2	n/a	0			
3	n/a	n/a	0		
4	n/a	n/a	n/a	0	
5	n/a	n/a	n/a	n/a	0

# An example

	1	2	3	4
1	0	1200		
2	n/a	0	400	
3	n/a	n/a	0	10000
4	n/a	n/a	n/a	0

A1 is 30x1

A2 is 1x40

A3 is 40x10

A4 is 10x25

$p_0 = 30$ ,  $p_1 = 1$

# Step 3: Computing the optimal costs

MATRIX-CHAIN-ORDER( $p$ )

```
1   $n = \text{length}[p] - 1$ 
2  Let  $m$  [1.. $n$ , 1.. $n$ ] and  $s$ [1..  $n-1$ , 2.. $n$ ] be new tables
3  for  $i = 1$  to  $n$ 
4       $m[i, i] = 0$ 
5  for  $l = 2$  to  $n$ 
6      for  $i = 1$  to  $(n - l + 1)$ 
7           $j = i + l - 1$ 
8               $m[i, j] = \infty$ 
9              for  $k = i$  to  $(j - 1)$ 
10                  $q = m[i, k] + m[k + 1, j] + p_{i-1}p_kp_j$ 
11                 if  $q < m[i, j]$ 
12                      $m[i, j] = q$ 
13                      $s[i, j] = k$ 
14 return  $m$  and  $s$ 
```

Complexity:  $O(n^3)$  Space:  $\Theta(n^2)$

# Step 4: Using S to Print Best Ordering

- ⦿  $s[i,j]$  is the split position for  $A_i A_{i+1} \dots A_j \rightarrow A_i \dots A_{s[i,j]}$  and  $A_{s[i,j]+1} \dots A_j$
- ⦿ Call Print-Optimal-PARENS( $s, 1, n$ )

**Print-Optimal-PARENS ( $s, i, j$ )**

**if ( $i == j$ ) then**

**print "A" +  $i$                     //+ is string concatenation**

**else**

**print "("**

**Print-Optimal-PARENS ( $s, i, s[i, j]$ )**

**Print-Optimal-PARENS ( $s, s[i, j]+1, j$ )**

**Print ")"**

# 16.3 Elements of dynamic programming

- **Optimal substructure**

- a problem exhibits **optimal substructure** if an optimal solution to the problem contains within its optimal solutions to subproblems.
- Example: Matrix-multiplication problem

- **Overlapping subproblems**

- The space of subproblems is “small” in that a recursive algorithm for the problem solves the same subproblems over and over.
- Total number of distinct subproblems is typically polynomial in input size

- Reconstructing an optimal solution

# Optimal structure may not exist

- We cannot assume it when it is not there
- Consider the following two problems. in which we are given a directed graph  $G=(V,E)$  and vertices  $u, v \in V$ 
  - P1: Unweighted shortest path (USP)
    - Find a path from  $u$  to  $v$  consisting of the fewest edges. Good for Dynamic programming.
  - P2: Unweighted longest simple path (ULSP)
    - A path is simple if all vertices in the path are distinct
    - Find a simple path from  $u$  to  $v$  consisting of the most edges. Not good for Dynamic programming.

# Overlapping Subproblems

- Second ingredient: an optimization problem must have for DP is that the space of subproblems must be “small”, in a sense that
  - A recursive algorithm solves the same subproblems over and over, rather than generating new subproblems.
  - The total number of distinct subproblems is polynomial in the input size
  - DP algorithms use a table to store the solutions to subproblems and look up the table in a constant time

# Overlapping Subproblems (Cont'd)

- In contrast, a problem for which a divide-and-conquer approach is suitable when the recursive steps always generate new problems at each step of the recursion.
- Examples: Mergesort and Quicksort.
  - Sorting on smaller and smaller arrays (each recursion step work on a different subarray)

# A Recursive Algorithm for Matrix-Chain Multiplication

RECURSIVE-MATRIX-CHAIN( $p, i, j$ ), called with( $p, 1, n$ )

1. **if** ( $i == j$ ) **then return** 0
2.  $m[i, j] = \infty$
3. **for**  $k = i$  **to** ( $j-1$ )
4.      $q =$  RECURSIVE-MATRIX-CHAIN( $p, i, k$ )  
       + RECURSIVE-MATRIX-CHAIN( $p, k+1, j$ ) +  $p_{i-1}p_kp_j$
5.     **if** ( $q < m[i, j]$ ) **then**  $m[i, j] = q$
6. **return**  $m[i, j]$

The running time of the algorithm is  $O(2^n)$ .

# The recursion tree

**for**  $k = i$  to  $(j-1)$

$q = \text{RECURSIVE-MATRIX-CHAIN}(p, i, k)$

+  $\text{RECURSIVE-MATRIX-CHAIN}(p, k+1, j) + p_{i-1}p_kp_j$

**RECURSIVE-MATRIX-CHAIN**( $p, 1, 4$ )

$i = 1, j = 4, k = 1, 2, 3$  ( $i$  to  $j-1$ )

needs to solve  $(1, k)$   $(k+1, 4)$

$k = 1 \rightarrow (1, 1)$   $(2, 4)$

$k = 2 \rightarrow (1, 2)$   $(3, 4)$

$k = 3 \rightarrow (1, 3)$   $(4, 4)$

# Recursion tree of RECURSIVE-MATRIX-CHAIN( $p, 1, 4$ )

- ⦿ This divide-and-conquer recursive algorithm solves the overlapping problems over and over.
  - ⦿ DP solves the same subproblems only once
  - ⦿ The computations in darker color are replaced by table loop up in MEMOIZED-MATRIX-CHAIN( $p, 1, 4$ ).
- ⦿ The divide-and-conquer is better for the problem which generates brand-new problems at each step of recursion.

# General idea of Memoization

- A variation of DP
- Keep the same efficiency as DP
- But in a top-down manner.
- Idea:
  - When a subproblem is first encountered, its solution needs to be solved, and then is stored in the corresponding entry of the table.
  - If the subproblem is encountered again in the future, just look up the table to take the value.

# Memoized Matrix Chain

```
MEMOIZED-MATRIX-CHAIN( $p$ )
1   $n \leftarrow \text{length}[p] - 1$ 
2  for  $i \leftarrow 1$  to  $n$ 
3      do for  $j \leftarrow i$  to  $n$ 
4          do  $m[i, j] \leftarrow \infty$ 
5  return LOOKUP-CHAIN( $p, 1, n$ )
```

LOOKUP-CHAIN( $p, i, j$ )

1. **if**  $m[i, j] < \infty$  **then return**  $m[i, j]$
2. **if**  $(i == j)$  **then**  $m[i, j] = 0$
3. **else for**  $k = i$  to  $j - 1$
4.            $q = \text{LOOKUP-CHAIN}(p, i, k) +$
5.                      $\text{LOOKUP-CHAIN}(p, k + 1, j) + p_{i-1}p_kp_j$
6.           **if**  $(q < m[i, j])$  **then**  $m[i, j] = q$
7. **return**  $m[i, j]$

# DP VS. Memoization

- MCM can be solved by DP or Memoized algorithm, both in  $O(n^3)$ 
  - Total  $\Theta(n^2)$  subproblems, with  $O(n)$  for each.
- If all subproblems must be solved at least once, DP is better by a constant factor due to no recursive involvement as in memorized algorithm
- If some subproblems may not need to be solved, Memoized algorithm may be more efficient
  - since it only solve these subproblems which are definitely required.

# Longest Common Subsequence (LCS)

- DNA analysis to compare two DNA strings
- DNA string: a sequence of symbols A,C,G,T
  - $S = \text{ACCGGTCGAGCTTCGAAT}$
- Subsequence of  $X$  is  $X$  with some symbols left out
  - $Z = \text{CGTC}$  is a subsequence of  $X = \text{ACCGCTAC}$
- Common subsequence  $Z$  of  $X$  and  $Y$ : a subsequence of  $X$  and also a subsequence of  $Y$ 
  - $Z = \text{CGA}$  is a common subsequence of  $X = \text{ACGCTAC}$  and  $Y = \text{CTGACA}$
- Longest Common Subsequence (LCS): the longest one of common subsequences
  - $Z' = \text{CGCA}$  is the LCS of the above  $X$  and  $Y$
- LCS problem: given  $X = \langle x_1, x_2, \dots, x_m \rangle$  and  $Y = \langle y_1, y_2, \dots, y_n \rangle$ , find their LCS

## LCS DP step 2: Recursive Solution

- What the theorem says:
  - If  $x_m = y_n$ , find LCS of  $X_{m-1}$  and  $Y_{n-1}$ , then append  $x_m$
  - If  $x_m \neq y_n$ , find (1) the LCS of  $X_{m-1}$  and  $Y_n$  and (2) the LCS of  $X_m$  and  $Y_{n-1}$ ; then, take which one is longer
- Overlapping substructure:
  - Both LCS of  $X_{m-1}$  and  $Y_n$  and LCS of  $X_m$  and  $Y_{n-1}$  will need to solve LCS of  $X_{m-1}$  and  $Y_{n-1}$  first
- $c[i,j]$  is the length of LCS of  $X_i$  and  $Y_j$ 
$$c[i,j] = \begin{cases} 0 & \text{if } i = 0, \text{ or } j = 0 \\ c[i-1, j-1] + 1 & \text{if } i, j > 0 \text{ and } x_i = y_j \\ \max\{ c[i-1, j], c[i, j-1] \} & \text{if } i, j > 0 \text{ and } x_i \neq y_j \end{cases}$$

## LCS DP step 3: Computing the Length of LCS

$$c[i,j]= \begin{cases} 0 & \text{if } i=0, \text{ or } j=0 \\ c[i-1, j-1] + 1 & \text{if } i, j > 0 \text{ and } x_i = y_j \\ \max\{ c[i-1, j], c[i, j-1] \} & \text{if } i, j > 0 \text{ and } x_i \neq y_j \end{cases}$$

- $c[0..m, 0..n]$ , where  $c[i,j]$  is defined as above.
  - $c[m,n]$  is the answer (length of LCS)
- $b[1..m, 1..n]$ , where  $b[i,j]$  points to the table entry corresponding to the optimal subproblem solution chosen when computing  $c[i,j]$ .
  - From  $b[m, n]$  backward to find the LCS.

# LCS DP Algorithm

LCS-LENGTH( $X, Y$ )

```
1   $m \leftarrow \text{length}[X]$ 
2   $n \leftarrow \text{length}[Y]$ 
3  for  $i \leftarrow 1$  to  $m$ 
4      do  $c[i, 0] \leftarrow 0$ 
5  for  $j \leftarrow 0$  to  $n$ 
6      do  $c[0, j] \leftarrow 0$ 
7  for  $i \leftarrow 1$  to  $m$ 
8      do for  $j \leftarrow 1$  to  $n$ 
9          do if  $x_i = y_j$ 
10             then  $c[i, j] \leftarrow c[i - 1, j - 1] + 1$ 
11                  $b[i, j] \leftarrow \text{“}\swarrow\text{”}$ 
12             else if  $c[i - 1, j] \geq c[i, j - 1]$ 
13                 then  $c[i, j] \leftarrow c[i - 1, j]$ 
14                      $b[i, j] \leftarrow \text{“}\uparrow\text{”}$ 
15                 else  $c[i, j] \leftarrow c[i, j - 1]$ 
16                      $b[i, j] \leftarrow \text{“}\leftarrow\text{”}$ 
17  return  $c$  and  $b$ 
```

**Figure 15.8** The  $c$  and  $b$  tables computed by LCS-LENGTH on the sequences  $X = \langle A, B, C, B, D, A, B \rangle$  and  $Y = \langle B, D, C, A, B, A \rangle$ . The square in row  $i$  and column  $j$  contains the value of  $c[i, j]$  and the appropriate arrow for the value of  $b[i, j]$ . The entry 4 in  $c[7, 6]$ —the lower right-hand corner of the table—is the length of an LCS  $\langle B, C, B, A \rangle$  of  $X$  and  $Y$ . For  $i, j > 0$ , entry  $c[i, j]$  depends only on whether  $x_i = y_j$  and the values in entries  $c[i - 1, j]$ ,  $c[i, j - 1]$ , and  $c[i - 1, j - 1]$ , which are computed before  $c[i, j]$ . To reconstruct the elements of an LCS, follow the  $b[i, j]$  arrows from the lower right-hand corner; the path is shaded. Each “↖” on the path corresponds to an entry (highlighted) for which  $x_i = y_j$  is a member of an LCS.

# Greedy Algorithms

- We have learned two design techniques
  - Divide-and-conquer
  - Dynamic Programming
- Now, the third → Greedy Algorithms
  - Optimization often goes through some choices
  - Make local best choices → hope to achieve global optimization
  - Many times, this works; Other times, does NOT!
    - Minimum spanning tree algorithms
  - We must carefully examine if we can apply this method

# An activity-selection problem

- Activity set  $S = \{a_1, a_2, \dots, a_n\}$
- $n$  activities wish to use a single resource
- Each activity  $a_i$  has a **start time**  $s_i$  and a **finish time**  $f_i$ , where  $0 \leq s_i < f_i < \infty$
- If selected, activity  $a_i$  take place during the half-open time interval  $[s_i, f_i)$
- Activities  $a_i$  and  $a_j$  are **compatible** if the intervals  $[s_i, f_i)$  and  $[s_j, f_j)$  do not overlap
  - $a_i$  and  $a_j$  are compatible if  $s_i \geq f_j$  or  $s_j \geq f_i$

# The greedy choice

- Intuition: Choose an activity that leaves the resource available for as many other activities as possible
- It must finish as early as possible: greedy
- Let  $S_k = \{a_i \in S : s_i \geq f_k\}$  be the set of activities that start after activity  $a_k$  finishes
- If we make the greedy choice of activity  $a_1$  (i.e.,  $a_1$  is the first activity to finish), then  $S_1$  remains as the only subproblem to solve.
  - **$a_1 + S_1$  , if  $S_1$  is the optimal solution for others  $\rightarrow a_1$  must be in the optimal solution**
  - **Is this correct?**

# Optimal substructure

- $S_{ij}$  is the subset of activities that can
  - start after activity  $a_i$  finishes
  - and finish before activity  $a_j$  starts
  - $S_{ij} = \{ a_k \in S : f_i \leq s_k < f_k \leq s_j \}$
  - $f_0 = 0$  and  $s_{n+1} = \infty$ . Then  $S = S_{0,n+1}$ , and the ranges for  $i$  and  $j$  are given by  $0 \leq i, j \leq n+1$
- Define  $A_{ij}$  as the maximum set in  $S_{ij}$ 
  - Selecting  $a_k$  in the optimal solutions generates two subproblems
  - $A_{ij} = A_{ik} \cup \{a_k\} \cup A_{kj}$
  - $|A_{ij}| = |A_{ik}| + 1 + |A_{kj}|$

# Converting a dynamic-programming solution to a greedy solution

- **Theorem 16.1** Consider any nonempty subproblem  $S_k$ , and let  $a_m$  be the activity in  $S_k$  with the earliest finish time:  $f_m = \min \{f_x : a_x \in S_k\}$ . Then  $a_m$  is used in some maximum-size subset of mutually compatible activities of  $S_k$
- Let  $A_k$  be the maximum-size subset of mutually compatible activities in  $S_k$
- Let  $a_j$  be the activity in  $A_k$  with the earliest finish time
- If  $a_j = a_m$ , we are done.
- Otherwise,  $A'_k = A_k - \{a_j\} \cup \{a_m\}$
- We have new  $A_k$  with  $a_m$

# An iterative greedy algorithm

GREEDY-ACTIVITY-SELECTOR( $s, f$ )

```
1  $n = s.length$ 
2  $A = \{a_1\}$ 
3  $k = 1$ 
4 for  $m = 2$  to  $n$ 
5     if  $s_m \geq f_k$ 
6         then  $A = A \cup \{a_m\}$ 
7              $k = m$ 
8 return  $A$ 
```

# Ingredients of Greedy ALs

- **Greedy-choice property**: A global optimal solution can be achieved by making a local optimal choice.
  - Without considering results of subproblems
- **Optimal substructure**: An optimal solution to the problem within its optimal solution to subproblem

# The End
